Question 1

Not answered

Marked out of 1.00

Question ID #10096: A meta-analysis of the research conducted by Baltes et al. (1999) found that, in terms of job outcomes, the compressed workweek has the least impact on:

Select one:

- ☐ A. overall job satisfaction.
- ☐ B. satisfaction with work schedule.
- ☐ C. supervisor performance ratings.
- ☐ D. objective measures of job performance.

The correct answer is D.

The compressed workweek decreases the number of days worked in a given work cycle by increasing the number of hours worked per day. For example, a compressed workweek might entail four ten-hour shifts rather than the usual five eight-hour shifts. In their meta-analysis of the research, Baltes and colleagues found that the compressed workweek had positive effects on supervisor ratings of employee performance, employee overall job satisfaction, and employee satisfaction with the work schedule. In contrast, the compressed workweek did not have a strong impact on objective measures of job performance or on absenteeism [B. B. Baltes et al., Flexible and compressed workweek schedules: A meta-analysis of their effects on work, *Journal of Applied Psychology*, 1999, 84(4), 496-513]. Note that these findings are not entirely consistent with earlier conclusions about the effects of the four-day (compressed) workweek, but the question is specifically asking about Baltes's research.

Answers A, B, and C: According to the research conducted by Baltes et al., in terms of job outcomes, the compressed workweek has the least impact on objective measures of job performance.
